Types of Structures

Natural and Manmade structures
Structures are all around us, some are natural like eggshells, spider-webs, caves and trees and others are man-made like bridges, towers, houses, shopping bags and cups. Structures are further divided into three other groups namely frame, shell and mass structures:

Frame Structures
A frame structure is a structure made up of many rigid parts joined together to form a ‘framework’. These different parts are called members.

Shell Structures
A shell structure is more enclosing than a frame structure - it surrounds and encloses something.

Solid/mass Structures
Solid structures rely heavily on solid construction such as masonry to support loads and to transfer these loads safely to the ground. Advantages of solid structures are that they are held in place by their own weight, losing small parts often has little effect on the overall strength of the structure.
- Mountains, caves and coral reefs are natural mass structures
- Sand castles, dams and brick walls are manufactured mass structures

Functions of structures

Supporting a load
A structure must be able to support its own weight and the load it has to carry. A load can be a person, an object or a force. A moving load is known as a dynamic load. A stationary load is known as a static load.

Spanning a gap
The most common structure fulfilling this function is a bridge. Bridges fulfills another function - supporting a load - they have to carry their own weight and the weight of whatever travels over them.

Enclosing people, animals or objects
All containers fulfill this function, as well as most buildings. Natural objects include shells, caves, hollow tree trunks etc.
Structural members

**Columns** are vertical structural members.

**Beams** are horizontal structural members. Beams often spread a load across two or more columns. How well the beam works depends on the material it is made from and its shape. Beams used in larger structures take many different forms, some are simply solid, some are hollow, and others have special cross-sections to provide strength and rigidity.

**A cantilever** is a structural member which sticks out like an arm from the main structure. A cantilever is a beam which is supported at one end only.

**A buttress** is a structure built against or projecting from a wall which serves to support or reinforce the wall.

**Arches**

The load at the top of the key stone makes each stone on the arch of the bridge press on the one next to it. This happens until the push is applied to the end supports or **abutments**, which are embedded in the ground.

The ground around the abutments is squeezed and pushes back on the abutments.

For every action there is an equal and opposite reaction. The ground which pushes back on the abutments creates a **resistance** which is passed from stone to stone, until it is eventually pushing on the key stone which is supporting the load.
**PROPERTIES OF STRUCTURES**

**Strength** - the capacity to withstand forces that tend to break an object or change its shape; it is an object's ability to hold its shape without collapsing.

**Rigidity** - the ability not to buckle or distort.

**Stability** - the capacity of an object to maintain or return to its original position; the state of being balanced in a fixed position. Why are some structures more stable than others?

We say that a structure has high stability if, when it is loaded, it tends to return to, or remain in, the same position. The degree of stability depends on the relationship between the base, the height and the weight of the structure.

The weight of an object is due to the force of gravity pulling down vertically on the mass of the object. The invisible position of the mass through which the force of gravity pulls is called the centre of gravity. If the position of the centre of gravity is low and lies well inside a large base area, the object is said to be very stable. If the centre of gravity lies to one side of the base area, the object is much less stable. If the centre of gravity is outside the base area, the object is very unstable and may require further support. A tall object tends to be unstable because its centre of gravity is in a very high position. Because of this, it can be more easily moved outside the base area by the application of external loads. A structure is said to be stable when it will not topple over easily when acted upon by a force.

**The relation between stability and centre of gravity**

The stability of a structure is related to the position of the centre of gravity for that structure. As indicated in the diagram below, as the structure is tilted, its centre of gravity rises. It is rotated about point b, caused by the pulling force.

![Diagram of a truss and lintels]

**Lintels** are beams made of concrete and reinforced with steel bars. They spread the weight of the structure above the opening of doors and windows to the structure beside them.

**A truss** is a structure made up of triangles.

![Diagram of a truss]

![Diagram of a lintel]
If the structure is stable, on release of the pulling force the structure will return to its original position. However, it must be noted that this will only be the case if the centre of gravity remains inside the base of the structure. When the structure is tilted to such a degree that its centre of gravity is outside its base, then the structure will become unstable as gravity acts on it and causes it to topple over.

**LET'S TRY IT!**

**Accurately determining the centre of gravity.**

Use a piece of thick card and cut out an irregular shape as shown opposite. Hang a plumb line from a pin as shown. Hold onto the pin and mark the position of the plumb line with a pencil. Repeat the process again twice, but each time place the pin at a different location, and mark the position of the plumb line string. Where the three pencil lines cross is the centre of gravity of the shape.
Some rules for stability:

- A low centre of gravity.
- A wide base is generally more stable than a structure with narrow base.
- The weight at the top of the structure should by less than the weight at the bottom.
- using struts, guys and stays to hold it
- using a foundation

It is not always possible to design structures that comply with these rules, and therefore sometimes special measures should be taken to make a structure stable. The tower crane is a long slender structure with a very thin base, and a very wide top. It has a large load to carry at the top at one end of the arm as indicated in the previous picture. A counter weight is placed on the opposite side of the crane arm to that of the. This system works by balancing the load with that of the counter weight.

**GUYS**
Structures like tents can also be made stable by anchoring it to the ground with guys. **Guys** are ropes, cables or chains (flexible members) that hold a structure firmly in place by pulling on it.

**STRUTS and TIES**
All structures have forces acting on them. Ties, guys and struts are structural members used to make structures stable. The part of the structure that has a tensile force acting on it is called a **TIE** and the part that has a compressive force acting on it is called a **STRUT**.

A tie (usually inflexible) holds other members in place by pulling on them. Many frame structures have members called struts (always inflexible). Struts hold members in position by pushing against them. Struts are made of materials like wood or steel which do not bend.

**STAYS**
A stay is a cable used to secure a mast (to keep a mast in place). Cable stayed bridges make use of stays as well as some pylons or high towers.
THE DESIGN OF FRAME STRUCTURES

If you look at some pictures of familiar frame structures like cranes, electricity pylons or roof supports you may notice that triangulation is used to make them rigid.

Making Structures Rigid

When forces are applied to a simple four-sided structure it can be forced out of shape quite easily. A structure which behaves in this way is said to be non-rigid.

By adding an extra bar or member (usually a strut) corners A and B are prevented from moving apart. The structure then cannot be forced out of shape, and is said to be rigid. Notice that the additional member has formed two triangles in the structure.

An alternative to triangulation is to use a gusset plate. A gusset is simply a piece of material used to brace and join the members in a structure. A triangular gusset plate has been used here but they can be made in a variety of shapes.

You will now do Resource Task 1 on page 12

Framed structures achieve most of their strength and rigidity from the way they are assembled. Most frameworks are built using a combination of struts and ties to make triangles. Triangles make very strong and rigid structures. Using triangles in this way is called triangulation.

Most shell structures achieve their strength and rigidity from the way they are shaped. Shell structures very rarely have large flat surfaces they tend to be designed and made with ribs to act as stiffeners. Egg and light bulbs containers are good examples. Both eggs and light bulbs can withstand considerable static forces if they are applied carefully. The same principle is used for corrugated iron.

Gussets are made of rigid materials such as wood or metal and is used to brace or hold frame members together.
Materials which are used to make structures, can be reinforced by using it in a different position. If two strips of are stuck to each other at a 90° angle, the cardboard will be stronger. The same happens to wood when it is laminated. The strips of the wood is glued together at an angle of 90°. A beam is also stronger when it is used in an upright position rather than flat.

**FORCES**

Forces can be either **static (stationary)** or **dynamic (moving)**.

**Static forces** are usually forces caused by the weight of the structure and anything which is permanently attached to it.

**Dynamic forces** are caused by things such as wind, waves, people, and vehicles. Dynamic forces are usually much greater than static forces and are very difficult to predict. These are the most common reason for structural failures.

An **external force** is a force placed on the structure from outside, by the wind perhaps or perhaps by someone sitting or standing on it. **Internal forces** are the forces which the structure must provide within itself to resist the external forces placed upon it. If the external forces are greater than the internal forces, a structure will collapse.

**Forces acting on and within Structures**

External forces or loads cause internal stresses to be set up in a structure. Not all forces or loads act in the same way. Forces can bend, pull, press, or twist. Each of these types of force are given special names.

- **Tension**: Is a force which tries to pull something apart. A structural member in tension is called a tie. A tie resists tensile stress.
- **Compression**: Is a force which tries to squash something together. A structural member in compression is called a strut. A strut resists compressive stress.
- **Bending**: Bending is a word you will have met before. A structure which is subjected to bending is being stretched and squashed at the same time.

**Bending**: A combination of forces that causes one part of a material to be in compression and another part to be in tension. In this picture a sponge with lines drawn on it is bent. You can clearly see how the lines at the top are moved closer together (in compression) and the lines at the bottom is pulled apart (tension).
Identifying structural members

Under load, a beam's top surface is pushed down or compressed while the bottom edge is stretched or placed under tension, the same happens to a column - one side will be in tension and the other side in compression. Struts are always in compression and ties are always in tension.

Paper Structures

What shapes are the strongest?

Use paper and fold 3-D shapes as shown to the right. Determine which shapes will be the strongest. Use the shapes as beams and columns and see which can hold the biggest load.

Try to make these shapes stronger, by reinforcing the paper and / or the structure.

You will now do Resource Task 2 on page 13
Help with structure building

**Strengthening**

joined together for added strength.

Sticky tape or elastic bands.

Flattened and woven together.

By laminating — sandwiching stronger layers.

Making a corner joint...

Reinforcing 2-D corner joints

Reinforcing 3-D corner joints
Capability Task

Your school received a rainwater tank from a sponsor and decides to make use of stored rainwater to water the school garden. Since you are learning about structures, your class is asked by the governing body to design and make models of water towers from which one will be chosen and handed over to building contractors to build the water tower.

Your facilitator will divide you into groups of 6. In your groups you have to decide together how you will solve the problem. Each group has to make one model for the water tower.

Given specifications

- The water tower must be a frame structure.
- The water tower must be stable, strong and rigid
- You may only use paper to make the structure
- The model must be 300 mm high
- You must use reinforcing techniques
- The model must be able to carry the weight of a 1 litre bottle of water
PORTFOLIO

INVESTIGATION

Resource Task 1

Use strips of cardboard and make these shapes. Use more strips and reinforce the shapes. Draw lines in the shapes below to show what worked.

Some members of the following structures are redundant. Use strips of cardboard and make these shapes, then remove some members and see which ones are redundant. Colour the redundant ones with your pencil.

Resource Task 2

Can you make a sheet of newspaper hold up a book? Explain how to do this.
